1 Introduction

Wine quality dataset is a dataset of red wines and white wines from the Vinho Verde region of Portugal by P. Cortez, A. Cerdeira, F. Almeida, T. Matos and J. Reis.[Cor+09]. They propose a data mining approach to predict human taste preference which is quantified as wine quality from 0 to 10. The input variables of the dataset is based on physico chemical tests including: fixed acidity, volatile acidity, citric acid, residual sugar, chlorides, free sulfur dioxide, density, pH, sulphates and alcohol. The model designed is useful to predict the wine tasting evaluations and improve wine production. Furthermore, it can also help wine industry model consumer tastes.

2 Formulation

Since the wine quality is rating in integers, it is a multiclass classification problem from 0 to 10. The input includes fixed acidity, volatile acidity, citric acid, residual sugar, chlorides, free sulfur dioxide, density, pH, sulphates and alcohol. All of them are float numbers. The output is the wine quality which can be considered as discretized labels. The statistic information of them can be found in the next section.

3 Datasets

This dataset is documented by UCI Machine learning Repository: <https://archive.ics.uci.edu/ml/machine-learning-databases/wine-quality/>. For the implementation, I concatenated white and red wines together. As we can see in 1, this is the first five lines of the white wine dataset. We can find the statistical information of the input data in 2. In this dataset, some property such as chlorides has mean as low as 0.056 while property such as total sulfur dioxide has mean as high as 115.745. We can notice that there are multiple attributes named with acid. Thus, the correlation between the attributes would be necessary. It can be found in 3.

| | fixed acidity | volatile acidity | citric acid | residual sugar | chlorides | free sulfur dioxide | total sulfur dioxide | density | pH | sulphates | alcohol | quality |
|---|---------------|------------------|-------------|----------------|-----------|---------------------|----------------------|---------|------|-----------|---------|---------|
| 0 | 7.0 | 0.27 | 0.36 | 20.7 | 0.045 | 45.0 | 170.0 | 1.0010 | 3.00 | 0.45 | 8.8 | 6 |
| 1 | 6.3 | 0.30 | 0.34 | 1.6 | 0.049 | 14.0 | 132.0 | 0.9940 | 3.30 | 0.49 | 9.5 | 6 |
| 2 | 8.1 | 0.28 | 0.40 | 6.9 | 0.050 | 30.0 | 97.0 | 0.9951 | 3.26 | 0.44 | 10.1 | 6 |
| 3 | 7.2 | 0.23 | 0.32 | 8.5 | 0.058 | 47.0 | 186.0 | 0.9956 | 3.19 | 0.40 | 9.9 | 6 |
| 4 | 7.2 | 0.23 | 0.32 | 8.5 | 0.058 | 47.0 | 186.0 | 0.9956 | 3.19 | 0.40 | 9.9 | 6 |

Figure 1: first 5 lines of the dataset

| | fixed acidity | volatile acidity | citric acid | residual sugar | chlorides | free sulfur dioxide | total sulfur dioxide | density | pH | sulphates | alcohol | quality |

Figure 2: Statistic information

Figure 3: Correlation between the attributes

| Algorithm | accuracy |
|----------------------|----------|
| Naive bayes Gaussian | 0.440 |
| K nearest Neighbour | 0.522 |
| XGB classifier | 0.548 |
| SVM rbf | 0.555 |
| Adaboost classifier | 0.577 |

Table 1: Cross Validation Score

We are preprocessing the data with the predefined function `fit_transform` from `sklearn` library. It is normalizing with formula:

$$\frac{x - u}{s}$$

where x is each attribute and u is the mean of the attribute and s is the standard deviation of the attribute.

4 Algorithm

In this project, I implemented several classic models for the multiclass classification problem including: support vector machine, XGBoost (gradient boosted tree), Naive Bayes Gaussian, K Nearest Neighbour, Decision tree classifier, Adaboost classifier and Logistic Regression. The original paper introduced three models: support vector machine, neural network and the multiple regression. In their comparison, SVM achieves highest score. In my implementation, Adaboost achieves higher score than SVC.

5 Experiments

The score of the cross validation is shown in tabular 1. The SVC achieves best performance with rbf kernel. Among all the models, Adaboost classifier achieves best performance.

```
[[ 0  0  5  2  0  0]
 [ 0  6 27 23  3  0]
 [ 1  1 40 14  4  1]
 [ 0  1 10 55 32  2]
 [ 0  0  4 11 14  1]
 [ 0  0  1 14 11 21]]
```

Figure 4: Adaboost classifier confusion matrix

| | | | | | | | |
|---|---|---|---|-----|-----|----|-----|
| [| [| 0 | 0 | 5 | 2 | 0 | 0] |
| | [| 0 | 0 | 37 | 21 | 1 | 0] |
| | [| 0 | 0 | 347 | 206 | 0 | 0] |
| | [| 0 | 0 | 129 | 538 | 24 | 0] |
| | [| 0 | 0 | 2 | 213 | 53 | 0] |
| | [| 0 | 0 | 0 | 36 | 11 | 0]] |

Figure 5: SVM confusion matrix

As we can see in the confusion matrix of SVM⁵, The model have low accuracy for the outer quality wines. This phenomenon is also noted in paper[Cor+09]. Compared to SVM, Adaboost⁴ fit the distribution better. It has a relatively high detecting rate for the outer wine quality.

6 Conclusion

With the development of the modeling algorithms, a better algorithm Adaboost is shown to better fit the true modeling of the wines. Also, XGBoost also shows a competitive performance compared to an old technique SVM.
